In November 2015, some 15 years after leaving the company, José Paim de Andrade Júnior returned to Rossi Residencial as Chairman of the Board. Considering the possible future paths the company could take, he decided to travel to Sumaré, a city near Campinas in the interior of São Paulo state, to see what had happened to one of the projects he had conceived when he was CEO of Rossi: the Villa Flora project.

¹ Case study developed by Sérgio G. Lazzarini, Luis Norberto Paschoal, Caroline Raiz Moron, Paula Macchione Saes, Leandro S. Pongeluppe and Nobuiuki Costa Ito. The authors would like to thank Rossi and Gira Sonhos for their contribution. This case study is solely for the purpose of classroom discussion and does not propose to render an opinion on managerial effectiveness or ineffectiveness or to serve as a primary source of data.

Inaugurated in 1999, Villa Flora was conceived as a planned neighborhood for lower-income classes. It drew inspiration from similar projects in the Philippines, Mexico and United States that Paim and João Rossi, one of the property developer's owners, had an opportunity to visit and study. The Villa Flora model, called *whole environment*, aimed to offer low-cost homes to lower-income segments, while still maintaining superior standards of quality, beauty, infrastructure and community integration compared to similar projects built by other Brazilian property developers. (Appendix 1). The model's implementation also included a comprehensive process to engage the community of residents to define the neighborhood's rules for coexistence and its governance.

Demand for the project was so intense that it ended up attracting segments of the public with higher incomes than initially planned. For instance, people who worked in Campinas, a larger city, started buying homes in Villa Flora seeking better quality of life during their leisure time. In the first three years alone, 774 units were sold, exceeding the initial expectations. The prices of the homes, which averaged around R\$35,000 in 1999, rose to around R\$100,000 by 2005.²

Villa Flora's success led Rossi to create the company Entreverdes to replicate the model in other locations. However, the new projects ended up following more along the lines of closed residential condominiums, without the open-neighborhood or community-based urban planning concepts initially envisaged for Villa Flora. Furthermore, in 2015, the mounting financial difficulties faced by Rossi Residencial and the need to divest certain assets led the group to put Entreverdes up for sale.

Once he arrived at Villa Flora on a Saturday afternoon, Paim parked his car and looked with admiration at the project he had helped conceive and build. Despite the potential divestment of Entreverdes, he couldn't keep himself from thinking the project could be explored by Rossi as a new line of urban and community innovation. Watching the people, of notably higher income than initially planned, circulate around the neighborhood, Paim also pondered if this would be the best market segment to pursue and if Rossi should go back to the original idea of focusing on lower-income communities.

Brazil's real estate industry in the 1990s

The early 1990s was marked by a severe shortage of capital for mortgage lending in Brazil. Furthermore, throughout the decade's first half, the economic scenario pressured the industry's growth due to the decline in real household income caused by rising levels of inflation, unemployment, interest rates and delinquency.

With the implementation, in 1994, of the Real Plan, the economy began to stabilize, with inflation declining and household income rising. Nevertheless, the international environment was affected by a series of turbulences. This sequence of crises forced the government to

² Villa Flora Sumaré: Planned Community. Presentation by Rossi Incorporação e Construção, [s.d.].

devalue the Brazilian currency and raise interest rates, which had adverse effects on household income and the availability of credit.

At that point, in the late 1990s, the federal government resumed the Housing Financial System (SFH) to help lower-income classes become homeowners through loans extended by the state-owned bank Caixa Econômica Federal or through private banks. However, to sell properties financed by the SFH system, real estate developers first had to invest in the site's basic infrastructure. Furthermore, the rule allowed the financing only of properties located in projects with no more than 500 units. In addition to being scarce, other mortgage lending alternatives had too many formal requirements. Typically, mortgage loans had terms of five years and only rarely reached ten years (in this case, only for higher-income homebuyers).

In addition to the challenges of obtaining a mortgage loan, local laws imposed restrictions on the creation of new communities, which varied from market to market. Some of the setbacks were related to the maximum number of units in any subdivision, the specifications for streets and sidewalks and rules for water, sewage and power infrastructure.

Despite the unfavorable economic scenario for the real estate industry, the Villa Flora project aimed to meet the demand from a population with market potential. Paim and João Rossi estimated that, at the end of the 1990s, Brazil had a housing deficit of around 13 million homes, which was concentrated in lower-income groups. A potential improvement in the Brazilian economic scenario, accompanied by the increased availability of mortgage lending, would create an opportunity to design and implement innovative projects for this class of homebuyers.

Villa Flora in Sumaré

Villa Flora in Sumaré consisted of the complete design and construction of a planned neighborhood. Conceived by José Paim during the 1990s, the project became a reality in 1999, based on the development of Rossi Residencial's proposal.

By observing the low-income homes traditionally built in Brazil, with all houses identical and no community engagement, Paim considered whether this type of housing was falling very short of the needs of its target public (**Appendix 2** – photos of the homes). Thinking about developing a new model, Paim, supported by João Rossi, drew inspiration from similar international experiences.

Based on a preliminary study of innovative projects in urban areas, Paim developed an interest in initiatives in the Philippines, Mexico and United States. In the Philippines, he visited various low-income condominiums created in response to the accelerated urbanization process that demanded rapid growth in the supply of housing for low-income populations. These condominiums consisted of small, low-cost houses but that featured attractive facades and common areas. From this experience, Paim learned how to combine simplicity and beauty, based on a strategy of planned expansion of the homes.

In Mexico, he visited large, open, low-income residential neighborhoods, each with more than 10,000 houses, which were all similar and integrated with the urban fabric. The homes received subsidized loans and therefore required more stringent control of the construction project's total costs. Inspired by the Mexican model, Paim sought cheaper construction methods and ways to structure the condominium to maximize synergies between public areas and private homes.

In the United States, he learned about the master plan community concept, which consisted of the comprehensive planning of the construction and management of a given city or neighborhood. Based on this concept, he understood the importance of an integrated design for the neighborhood and of organizing the local community into homeowners' associations. Appendix 3 presents the characteristics and Appendix 4 shows photos of some of these international projects.

In essence, the Villa Flora project combined elements of these international experiences. Its core idea was to create a planned community with the characteristics of a complete "microcity." To achieve this, Paim developed a model he called *whole environment*, which involved the integrated planning of the urban space and full community integration. Rossi's advertising materials introducing the whole environment concept at the time are shown in Appendix 5.

Villa Flora's whole environment concept

To Paim, the main objective of Villa Flora was to build a planned neighborhood that offered quality of life and social coexistence. In its essence, the whole environment model combined three innovative elements from Brazil's housing market: urbanism, environment and community life. From urbanism, it drew on the concern for everything that would be built around the home, such as paved streets and sidewalks, public lighting, water and sewage treatment systems, and even the installation of fundamental elements to create a high-quality neighborhood, such as a sports club, local commerce, a school and a church. In terms of environment, the proposal was to preserve large green areas with environmental value by building squares and parks and making common areas more pleasant. The concept of community life was innovative in the sense that it encouraged social interaction. To make this possible, an association of local homeowners in Villa Flora was created that would manage the neighborhood and ensure the application of well-defined rules for coexistence and interaction.

According to Paim, establishing clear rules to be observed collectively was critical for guaranteeing the project's architectural aspect and the high quality of social coexistence. One of his concerns was to prevent each homeowner from renovating their homes and changing its façade or external and common areas, which almost always occurred in the low-income

projects at the time, such as those managed by CDHU³ or Inocop.⁴ So, inspired by the models of planned cities, Paim opted for a style with a common architectural standard to follow, while carefully planning the design so that each home would not appear a mere clone of the others. Drawing on the Filipino model of planned expansion, each home included an expansion project, but which must stringently follow the previously established options.

One of the major challenges for the project's success was to attract a public that would value the importance of living in community, since each home would not have large amounts of internal floor space. Until then, condominiums and housing projects favored a lifestyle focused on the interior environment, in which each homeowner would design their project individually and create private living areas (such as large backyards with swimming pools and barbecue areas).

Meanwhile, the Villa Flora project provided for the creation of an association of homeowners, who would effectively become the administrators of the community. Each home would pay a small mandatory monthly contribution for any expenses with improvements and renovations. Moreover, covenants, conditions and restrictions would establish rules governing coexistence, such as requiring cars to respect pedestrians and rules for renovating and expanding each independent unit. Homeowners must obey the rules established, not change the architectural style of facades and gardens and preserve the integrated planning of the area.

Nevertheless, Paim believed that a homeowners' association alone would not suffice to ensure the success of this model based on high community engagement. He believed it would be essential to ensure a full understanding that the space, whether private or public, was everyone's responsibility. In his own words, "either homeowners protected [the model] or everything would collapse within one year."

Partnership with Gira Sonhos

Paim realized that he would need help to create this value of community life and to engage local homeowners, especially the first ones. After their initial engagement, they would help preserve the collective ideal. To implement this process of collective construction, he forged a partnership with Gira Sonhos, a non-governmental organization (NGO) founded in 1995 by a multidisciplinary team of researchers, artists and educators with the mission of:

³ The São Paulo State Housing and Urban Development Company (CDHU) was created in 1949 and is connected to the State Housing Department. Its objective is to execute housing programs exclusively targeting low-income populations. CDHU. Presentation. Available at: <http://www.cdhu.sp.gov.br/a_empresa/apresentacao-cdhu.asp>. Accessed on: Mar. 7, 2016.

⁴ The Institute to Guide Housing Cooperatives (Inocop) is present in various Brazilian states and started operating in the mid-1960s. It operates using own projects and funds transferred by financing agents and works to provide advisory services to housing cooperatives. It is recognized for its low prices and facilities for acquiring properties. INOOCOP-Sp. Available at: <<http://www.inocoop-sp.com.br/o-inocoop-sp#.Vt177dxBSUk>>. Accessed on: Mar. 7, 2016.

Raising awareness on the importance of revitalizing and integrating human values into the various levels of society, such as education, communities and organizations, based on collaboration, friendship, happiness, respect, co-creation and awakening the personal talents of each individual.⁵

The partnership was to last five years and aimed to encourage the integration of local homeowners, implement the community's governance and develop collective values grounded in interpersonal coexistence. Gira Sonhos emphasized among homeowners that appreciation in their property values depended on the quality of the local environment. After five years, Villa Flora would enjoy the conditions needed to manage itself and uphold the established standards. The work of Gira Sonhos would start by training realtors to convey the concept from the moment of sale. Then, members of the NGO would conduct educational and social events (such as traditional festivities and gatherings) in an effort to build a sense of collective belonging. They also would be responsible for organizing, managing and mediating the homeowners' association in the first few years, while working to develop local leaders.

To foster participation and interaction among homeowners and demonstrate their importance, Gira Sonhos based its efforts on the principle of "living and interacting," supported by the notion that you must first learn about people's origins and culture in order to organize a new community. Aware of the difficulties involved in leading different people to learn to live collectively and follow pre-established rules, the NGO also planned actions with the community's children so that they could help to solidify collective values among their parents.

Cláudia Pellegrino, from Gira Sonhos, explains that the NGO applied a "living methodology" that varied from case to case. According to Cláudia, the four basic pillars were: "emotionality" (living and interacting), "managerial vision" (vision of the collective, participatory management), "social network" (decentralized vision of power) and "social capital" (valuing the experience of human values) (Appendix 6). All pillars articulated what Claudia called an "amalgam of lightheartedness": the idea was to create mechanisms to foster lighthearted dialogue, while always striving for civility in social interactions and strengthening relationships. This aspect was to be present in all activities organized, because, otherwise, people would lose interest and the proposed goals would be lost. According to Cláudia:

What are you buying when you buy a house or apartment? An empty box. So what are you buying if everything is empty? Dreams, sensations, interpersonal relations.

This ensured that all education efforts to develop human values were fully aligned with the model of whole environment envisioned by Paim. Villa Flora proposed reclaiming the quality of life of small towns, creating special spaces for living and encouraging life in a community and social integration.

Executing the Villa Flora project

The next step would be to create the mechanisms to ensure the project's fruition and proper execution. Villa Flora would not be a closed condominium, with the sale of lots or the construction of homes by private individuals, but an entirely planned neighborhood, which would require special precautions during its implementation process.

The first step taken to carry out the project would be to choose a space that could accommodate it. The interior of São Paulo state was attractive to Rossi Residencial because of its large uninhabited areas with cheaper land prices than in the state capital. The Campinas Metropolitan Area was especially attractive because it not only was an important economic hub in the state, but also was home to a Rossi branch office. Various other municipalities in the Campinas region, such as Paulínia and Jaguariúna, were consulted to assess their interest in the project. Among the options, Sumaré proved the most viable. A fundamental aspect was the support of the municipal government, which saw in the project a chance to attract investment to the city and showed some flexibility in amending local laws to ensure the project's feasibility. Moreover, because of its short 20-minute distance from Campinas, the city serves as a commuter town for those working in that metropolitan area, which could mean higher demand for the properties.

After selecting the city, the next step was choosing the site for building Villa Flora. The real estate project would not follow the market standards customary at the time. While contractors and property developers typically partnered with the owners of available areas, paying them with the transfer of finished units, Paim believed the only way to ensure the project's success would be to acquire the entire property for the planned neighborhood. In this way, Rossi Residencial would commit to the project from start to finish, since the company itself would be responsible for planning and building the entire condominium project. The lot acquired was called the Quilombo Farm, with an area of 800,000 square meters. At the time, the land cost four *reais* per square meter, much less than the average of other cities in the region.

Drafted under the leadership of Luciano Borguesi, the director in charge of structuring Villa Flora, the initial design envisaged the construction of 4,200 residential units, all with front yards open to the street, a backyard and individual parking. The houses would be divided into more than 40 condominiums that would form the neighborhood. The public areas, parks and squares would occupy 173,000 square meters, double the original space required by local regulations. The neighborhood's design was also unique: streets would be wider and curvy to avoid the impression of monotony, while sidewalks would be high quality and feature accessibility. There would be three types of condominiums characterized by the size of the homes or apartments (from 42 to 70 sq. m.), the number of bedrooms (from one to three) and the initial sales price (from R\$25,000 to R\$46,000). Paim believed the choice of architectural style should address the desire of future homeowners and not convey the idea of an artificial city or a "movie set." The solution chosen was a style inspired by Iberian architecture, since it combined colonial Portuguese and Spanish styles, which are very common in Brazilian

architecture. In the advertising material, Rossi guaranteed the quality of the properties, their durability and the delivery of a dream (Appendix 7). In the words of Luciano Borguesi:

The product was to create a high-quality ambience and the feeling of belonging to a place; the subproduct was the home to sell.

Unlike the construction of residential condominiums or subdivisions, the plan was to build a small urban center starting with a main square and church, followed by local commerce and then actual houses. Appendix 8 shows the initial map of the neighborhood. Villa Flora would have to be integrated into the urban network of Sumaré, but also have a division between the planned neighborhood and the rest of the city. As a result, walls were built around the entire project, with access through a single entrance, but with free access by the general public to the neighborhood.

Some challenges emerged for Luciano Borguesi and Paim, together with Rossi, over the course of the project's implementation. Before authorizing the project, the Sumaré municipal government required the construction of the entire basic sanitation system of the site using own resources before selling the first homes. Furthermore, the law required the completion of all infrastructure (i.e. roads, power lines, water and sewage) within four years. This required a high initial investment that, in the case of Villa Flora, took a long time to be used completely. Normally there was one condominium under construction and another two for sale at any given time, and construction of the next one would start only when the previous one was sold. The last units were built ten years after the first ones.

Moreover, the economic scenario in Brazil was unstable and real estate credit was not widely available from state-owned or private banks. Nevertheless, the first houses in Villa Flora began to be sold in 1999. After an intense advertising and marketing effort, the project's commercial launch was a success. Rossi Residencial had invested in advertising Villa Flora Sumaré until it sold the first 200 units of the project, which was achieved quickly. After achieving this mark, advertising was limited to "word of mouth." To encourage and disseminate knowledge of and interest in the new planned neighborhood, Rossi began offering a cash reward to current homeowners in Villa Flora for each unit sold based on their personal recommendation. This drove sales by recommendation to account for 30% of all sales, which is much higher than in other Rossi projects, where this figure has never surpassed 10%. As a way to pay homage to the "pioneers," a plaque was made with the names of the first 200 homeowners, which was displayed at the project's entrance.

The initial sales success led the company to realize that, as time went by, the public interested in buying homes in the neighborhood had higher incomes than initially expected. The neighborhood's security, facilities and quality of life interested people in the region, who demanded larger homes than those initially planned. The project to build 4,000 homes was reformulated and adjusted to 3,473 in a total of 49 condominiums. The most recent units was built to a higher standard, with homes ranging from 85 to 123 square meters and, in 2005, priced from R\$100,000.

Appendix 9 shows the number of units sold every year by Rossi in Villa Flora Sumaré. The highest flow of sales was in the ten-year period from 1999 to 2008, with the peak in 2007, when 540 units were sold. From the year of the commercial launch through 2015, total revenue adjusted for inflation came to R\$500.0 million.⁶

Part of the project's success is explained by the community engagement generated by the homeowners' association and by the work of Gira Sonhos. As initially planned, the NGO helped raise awareness among homeowners about not just respecting, but also ensuring respect for the community's values. In this way, the initiatives such as workshops, group dynamics and courses helped develop and strengthen values such as respect, social interaction and community life. Also as planned, the Homeowners' Association of Villa Flora Sumaré was created, guided by the following motto:

The balance of the individual depends on the balance of the community.⁷

The association's goal was to integrate homeowners and ensure compliance with the rules, while encouraging coexistence in the community. In addition to representing homeowners before the government, the association organized social integration events such as regional and Christmas parties and meetings to address the general issues of the neighborhood. In the words of some of the homeowners:

Here, everyone knows each other and there are many activities organized by the association. There's a playground in the square, a barbecue area and a party hall. It's very tranquil here. The neighbors know each other, there's no crime and the children can play on the streets.

Replicating the project and creating Entreverdes

After Paim left the company, in the mid-2000s, the initial sales success of Villa Flora Sumaré became an attractive model for Rossi Residencial, which saw a business opportunity in the model. Mortgage loans became more accessible, especially due to the growing credit available under the SFH system for lower-income homebuyers and the innovations in mortgage loans, such as fiduciary sale.⁸ Just as important, in 2003, Brazil was starting to show improvement in its macroeconomic indicators, with good prospects for economic growth and lower interest rates.

⁶ Data in the paragraph provided by Rossi Residencial.

⁷ Homeowners' Association of Villa Flora Sumaré. Available at: <<http://www.amvfsumare.com.br/historico.html>>. Accessed on: Feb. 19, 2016.

⁸ The fiduciary sale of real estate was introduced by Federal Law 9,514, of 1997, Articles 22 to 33. Fiduciary sale is the transfer of the ownership of a movable asset or real estate from a debtor to a creditor to guarantee the performance of an obligation and it occurs when a buyer uses a loan to buy an asset. This change in the model of real estate financing was suggested by João Rossi himself, during meetings with government officials. João Rossi's main goal was to create a loan model that enabled the out-of-court performance of contracts by those in default. In other words, a model that prevented foreclosure on the property of individuals in default with their obligations without the process being subjected to traditional court proceedings, which take eight to ten years to be concluded.

As a result, in the mid-2000s, Rossi Residencial started construction on another two Villa Flora projects, which, despite maintaining the name, ended up differing from the model that had been built in Sumaré. These projects were Villa Flora Votorantim near Sorocaba, a city in the interior of São Paulo state, which was launched in 2008 (**Appendix 10**), and Villa Flora Hortolândia, located some 15 km from Villa Flora Sumaré, which was launched in 2009.

To begin with, the higher land prices in both regions did not allow the property developer to purchase such a large area as in Sumaré. However, the smaller property was attractive to the company, since it would reduce its costs with infrastructure and shorten construction. At Villa Flora Hortolândia, 1,018 houses and 336 apartment units were built. In Votorantim, in addition to a commercial condominium project, 1,322 houses and 470 apartments were built.

One important difference between the original Villa Flora and the new projects were their security systems. Instead of an open neighborhood, such as the one in Sumaré, both projects were built as closed condominiums, with access controlled by a gated entrance.

Despite these differences, Rossi Residencial maintained its partnership with Gira Sonhos to help implement the project. However, according to the NGO, the work methodology adopted in Votorantim and Hortolândia was slightly different from the Sumaré experience. First, Gira Sonhos realized the importance of shortening the project from the five years that the first experience took. To do so, activities would have to be led differently to ensure greater engagement by homeowners in the execution and planning of activities. In Sumaré, the NGO had been responsible for the entire organization, creation and execution of works. Cláudia Pellegrino, from Gira Sonhos, argued:

The sooner people become engaged and self-manage the project, the sooner we can leave. We operated in a very centralized and matriarchal way in Sumaré. We learned we had to do less and mediate more in the other cities.

Despite the construction of another two neighborhoods under the Villa Flora model, Rossi Residencial stopped investing in the model in the following years. In 2013, the company created Entreverdes Urbanismo, a company focused on building high-income land subdivisions that combined urban planning with the concept of a private neighborhood. This meant that the property developer was straying further from the Villa Flora model and following a more traditional model of closed condominiums targeting higher-income segments.

Returning to Villa Flora

From inside his car, Paim recalled everything that led to the creation of Villa Flora and wondered how Rossi could take advantage of the project's experience. He was returning to the company at a critical time – Rossi had been in crisis since 2011, with accumulated net losses of R\$938 million and debt of R\$3.1 billion.⁹ A large part of these problems was attributed to the growing supply of apartments at a time of slowing sales and mounting cancellations by homebuyers. Accordingly, one of his missions would be to help restructure the company and define a new strategic direction to support a path of growing profitability and declining debt. As part of a set of short-term initiatives, the divestment of Entreverdes was considered, since it was a profitable unit whose divestment proceeds could help reduce existing debt.

Even so, Paim wondered if the development of innovative urban projects could be a part of Rossi's future strategy. As the project's idealizer, to him, Villa Flora was not just a unique product, but also an important innovation in terms of urban design and community interaction. After leaving his car and talking to several homeowners who were enjoying the pleasant Saturday afternoon, Paim realized just how much Villa Flora was an appreciated and valued place. As he walked through the neighborhood, he could not help but ask himself if the idea once again could become a strategic project for Rossi. Would it be possible to replicate Villa Flora as originally conceived? Should it target lower-income homebuyers or position itself more like an urban innovation project for those who could afford it? How do you transform Villa Flora into an economically feasible project and, at the same time, have a significant impact on communities?
